Bat collisions at secondary roads: the importance of bat density and flight behaviour

Charlotte Roemer

MNHN / Biotope

Environmental impact assessment studies

- **Mandatory** in Europe for roads and in some countries (France) for wind farms
- 3 steps after a field diagnosis

Environmental impact assessment studies

- **Avoid:** most efficient step, but often neglected (Bigard et al., 2017)

- Lack of empirical evidence

Bats: a unique sensory-motor system

- Bats use landscape structure for orientation and foraging
→ How does it influence intraspecific collision risks ?

N. noctula

M. daubentonii

P. pipistrellus

M. mystacinus

Influence of the environment on bat collisions

- Collisions **↗** in **late summer and autumn**

- **Good quality habitats** **↗** collisions

→ Scarce information at the species level

→ Role of vegetation orientation and density ?

Conditioning events of collisions

Carcasses counts

Acoustic recordings

Collisions =

Number of individuals present on site

X Risky behaviour

Advantages of bat acoustics over bat carcasses counts

- More data
 - More information at the species level
 - Higher statistical power
- Information on behaviour
 - Detailed understanding of collisions
 - Basis for siting of reduction measures

Objectives

- Test effect of different landscapes on (1) **bat density** and (2) **flight behaviour**
- Infer **collision risks**
- Give recommendations for **road micro-siting/siting of mitigation measures**

Methods

Methods

- Disentangling the conditioning events of collisions:

PROXY

(1) Bat density ← number of bat passes/night

1 bat pass = acoustic contact of the species in a sequence of 5 sec (Barataud, 2015)

Methods

- Disentangling the conditioning events of collisions:

(2) Bat movement behaviour

→ Proportion of flight trajectories in the zone at collision risk

Collision risk

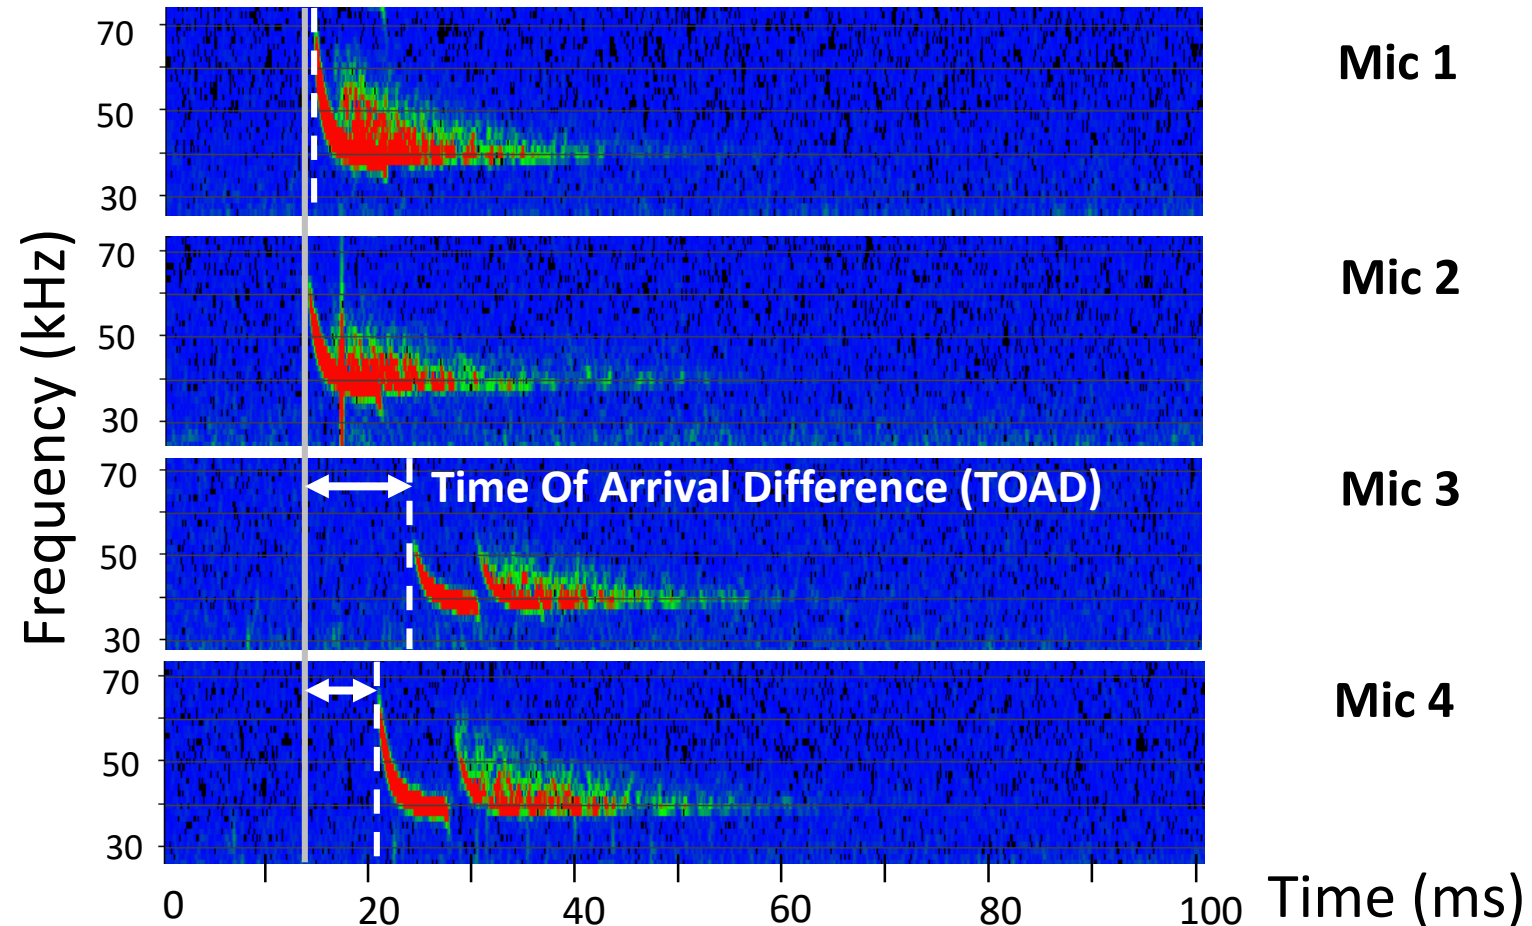

Safe

Methods: 3D acoustic flight path tracking

- Road collision risks studied on operational secondary roads
- Range of observation 10 m

Methods: 3D acoustic flight path tracking

Proportion of
flights in the zone
at collision risk

Methods: descriptive variables

- 6 different local landscapes
- Distance between road and tree foliage
- Vegetation height
- Road traffic
- Time of the year

Forest

Double parallel
tree rows

Forest edge

Simple parallel
tree row

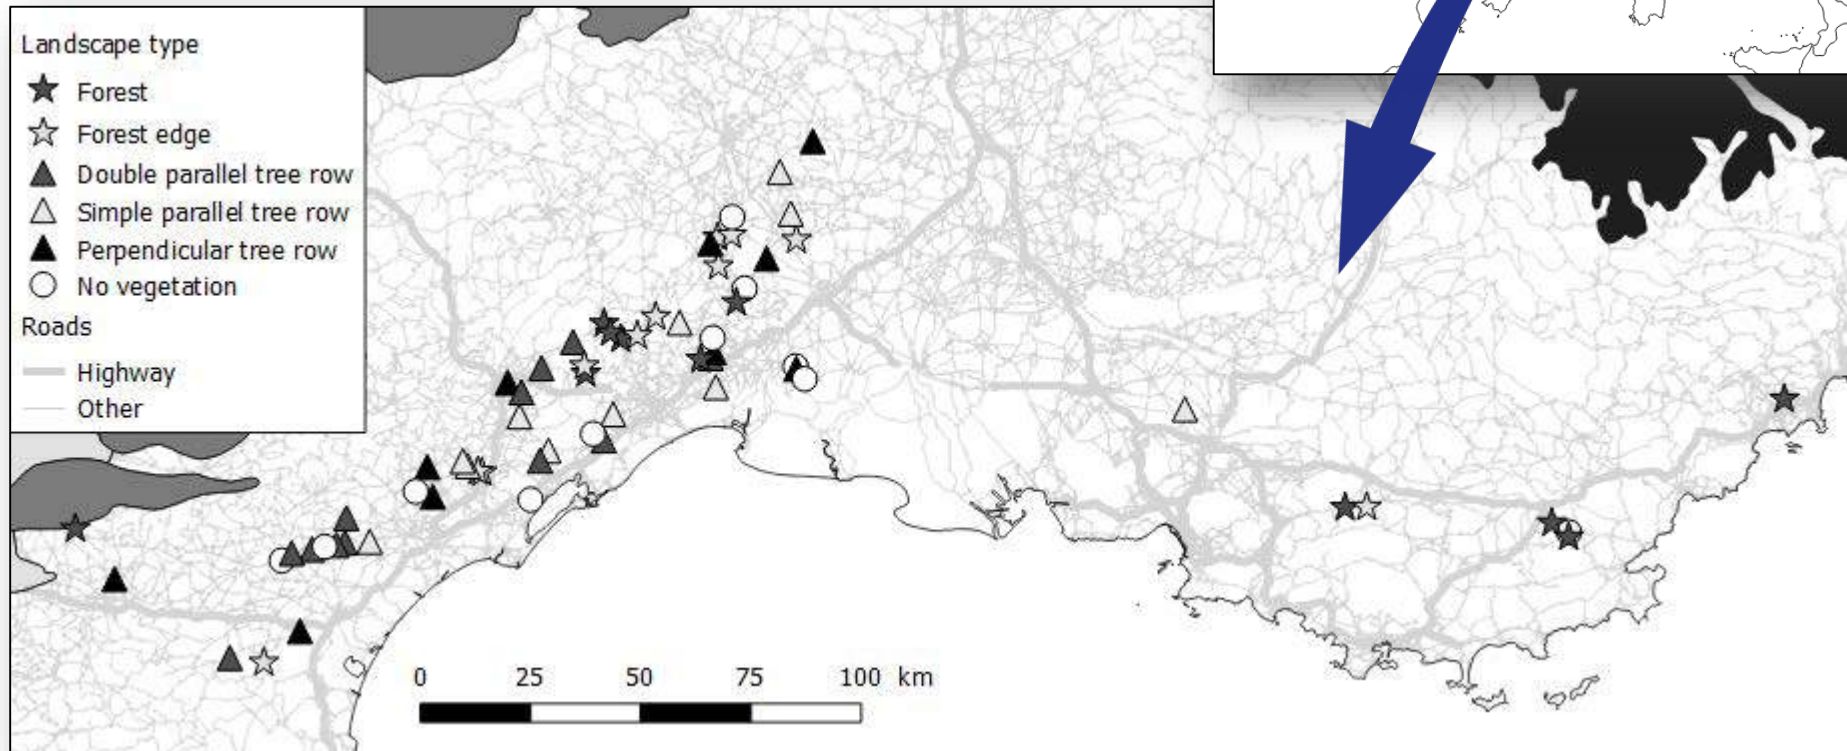

Perpendicular
tree row

No tree

Methods

- 66 study sites in French Mediterranean region
- 2016+2017
- >2 full night recordings/site

Methods

**Collision
risk =**

Species density

X

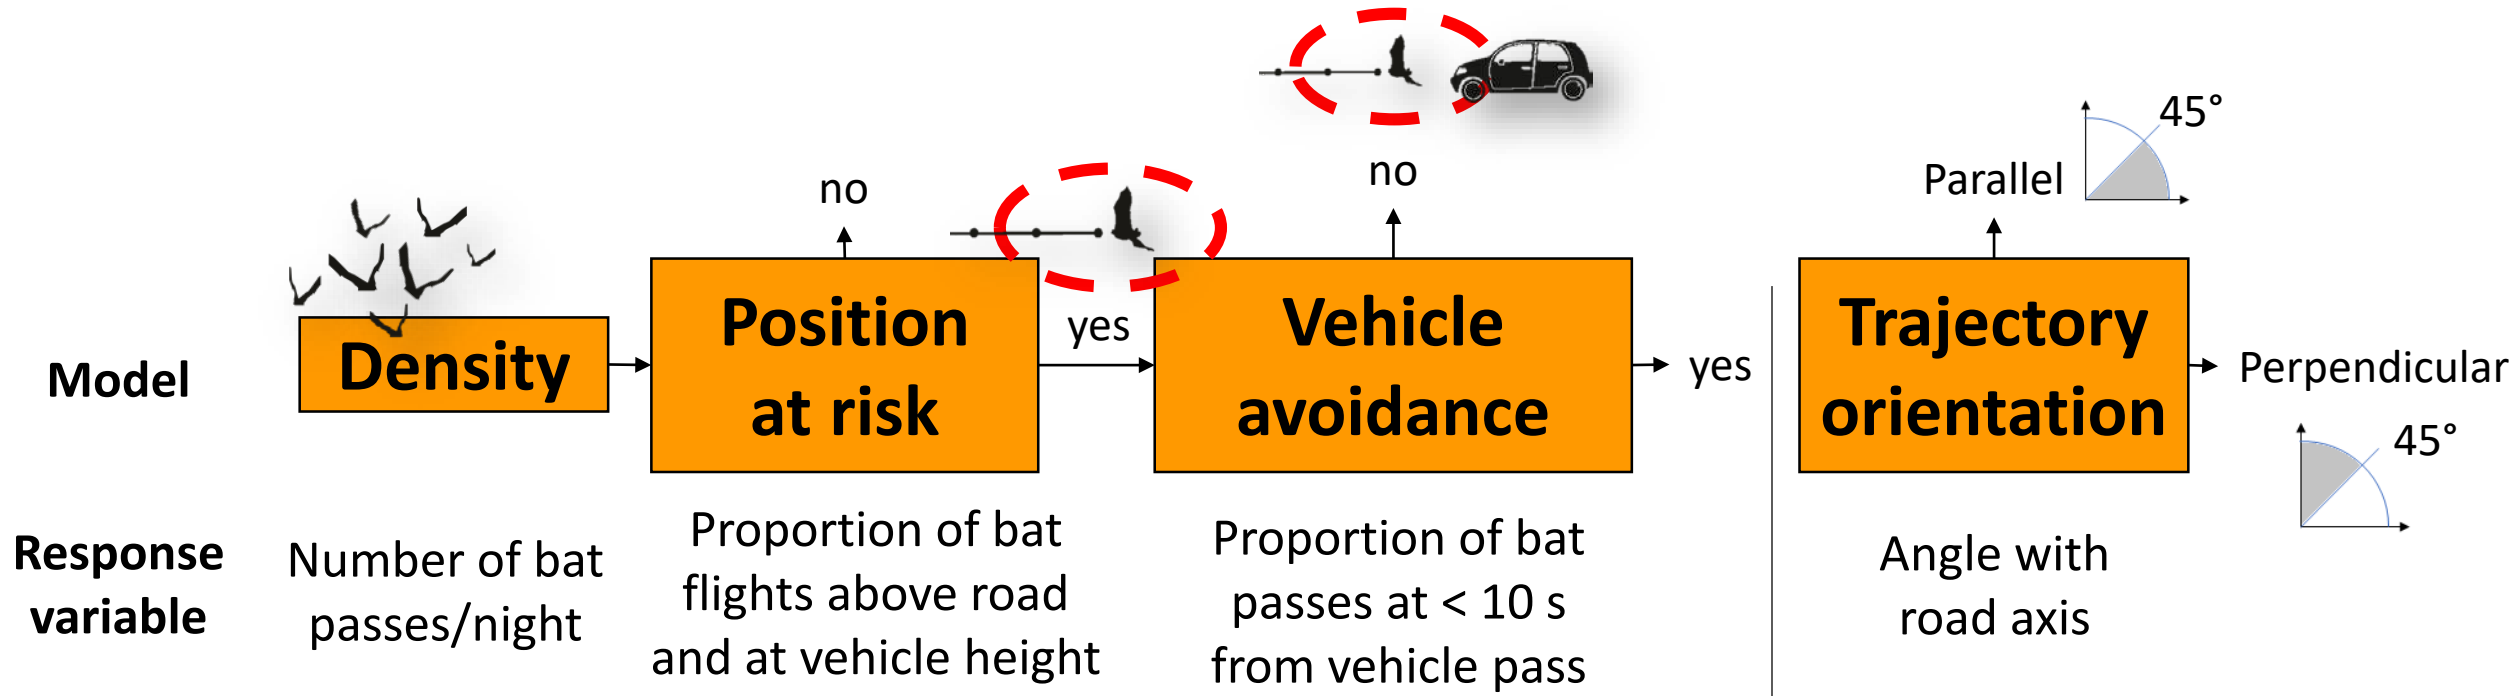

**Proportion of flights
in the zone at risk**

X

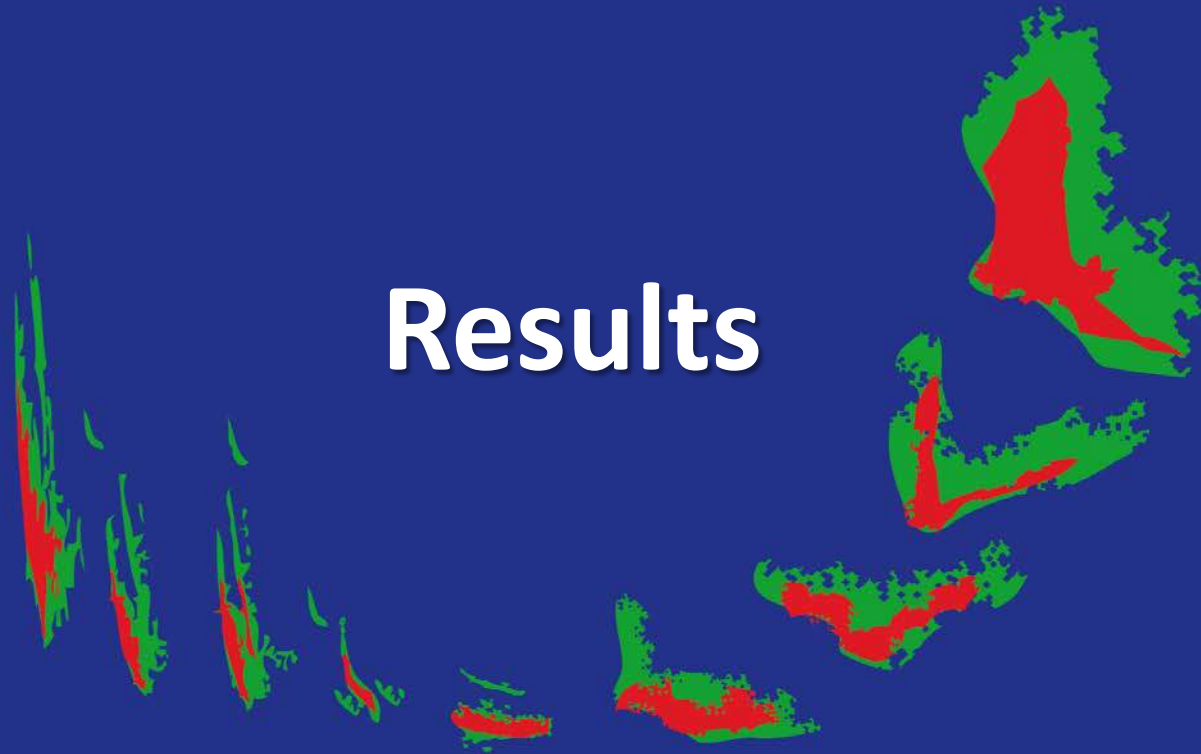

**Proportion of flights
in the zone at risk
not avoiding vehicles**

Methods: Generalised linear mixed models

Results

Results

- **122,294 bat passes** recorded and identified
- **30,954 flight trajectories**
- Models for:
 - 9 species
 - 3 groups (*Pipistrellus kuhlii/nathusii*, *Plecotus* sp. and *Myotis blythii/myotis*)
 - 3 guilds:
 - **Short-range echolocators:** *Myotis*, *Plecotus*, *Barbastellus* and *Rhinolophus*
 - **Mid-range echolocators:** *Miniopterus*, *Pipistrellus* and *Hypsugo*
 - **Long-range echolocators:** *Eptesicus*, *Nyctalus* and *Tadarida*

H. savii

E. serotinus

N. leisleri

Distance to tree foliage

Tree height

↗ primary productivity = ↗ bat density ?

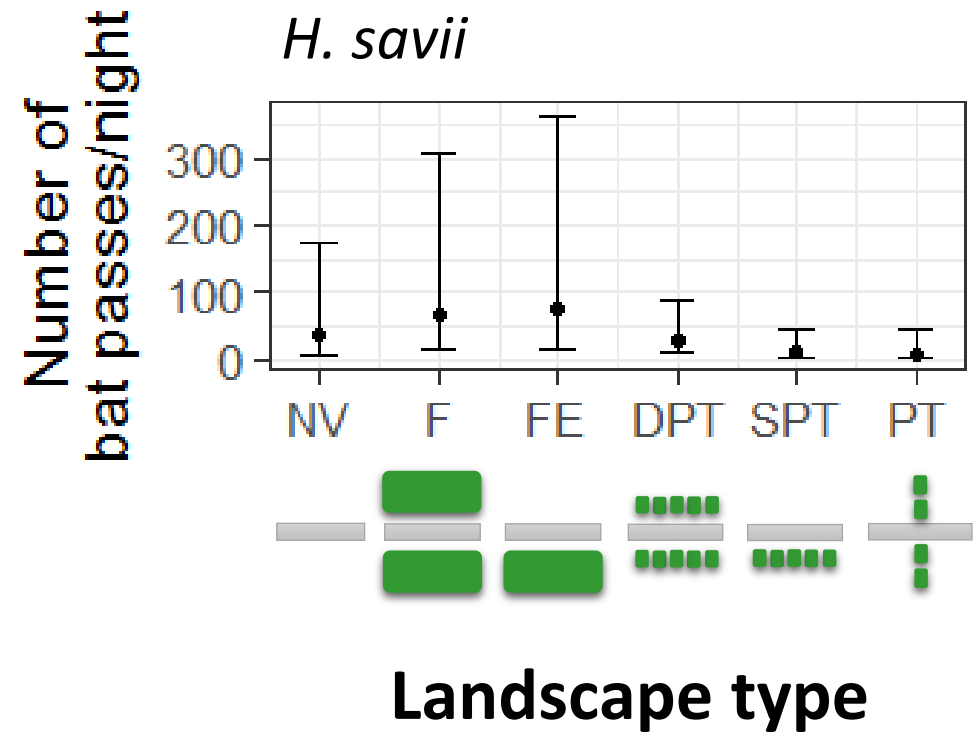

Traffic

Landscape type

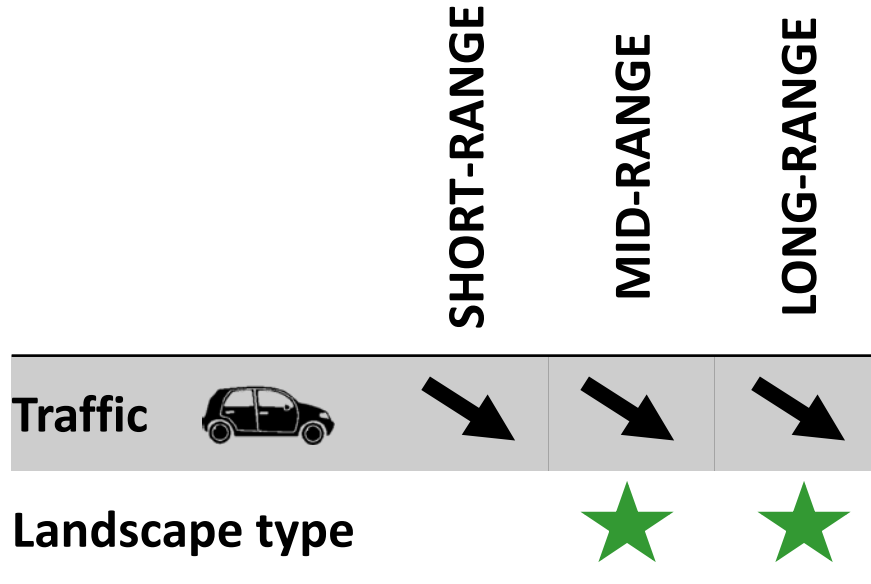

Results

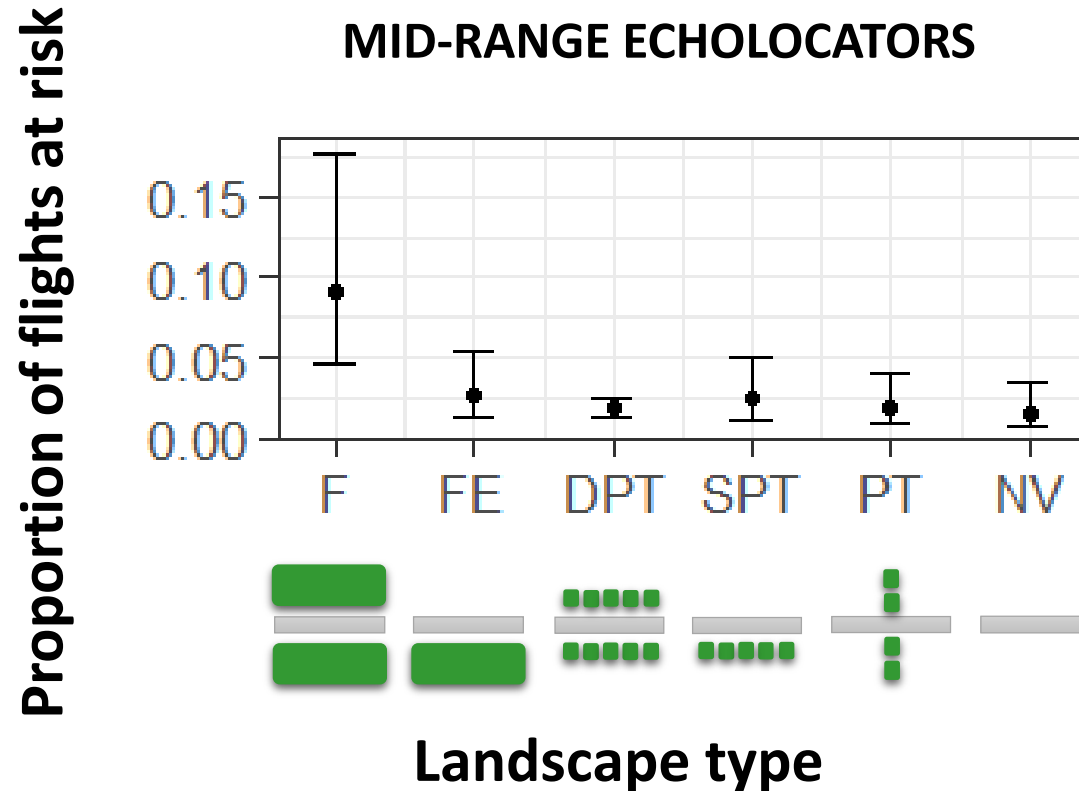

- Responses varied according to species ecology (diet, roost opportunities...)

Results

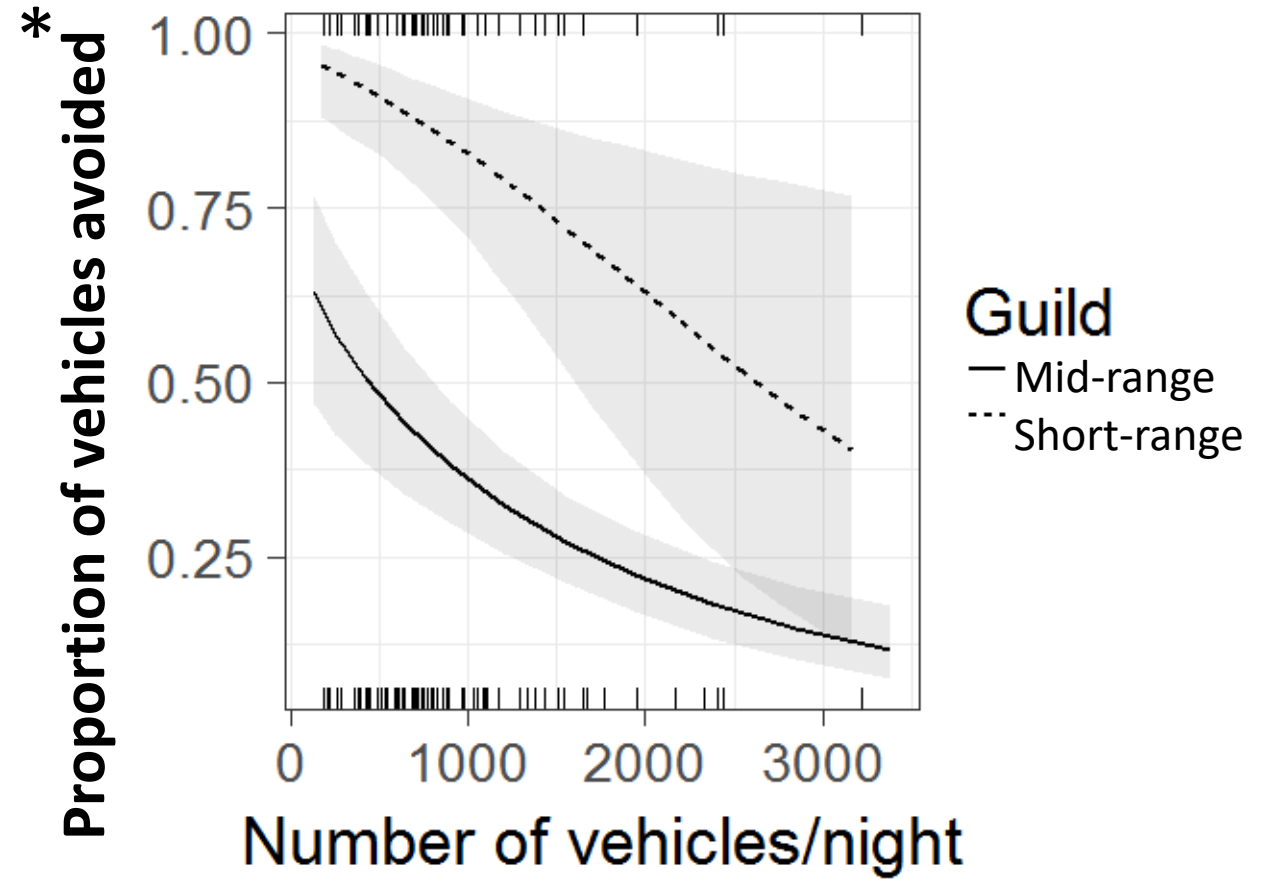

Bats avoid flying above the road with ↗ traffic

Results

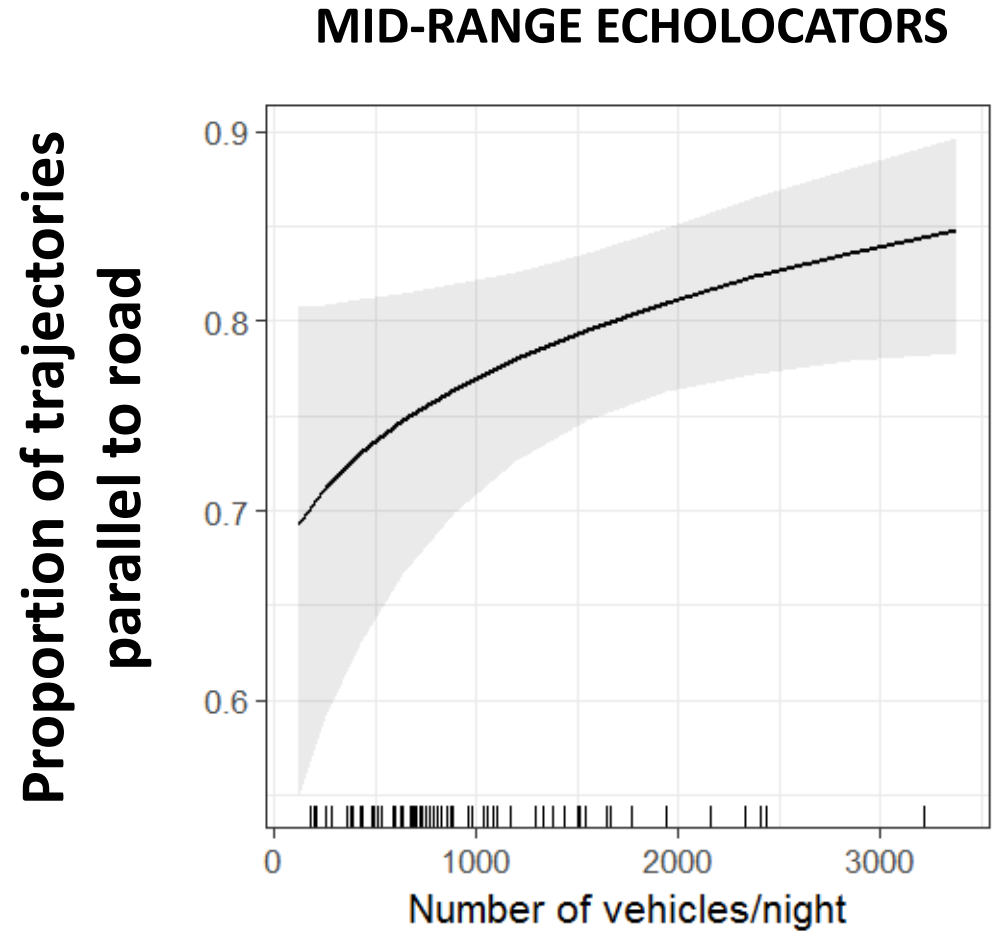

- **Similar response for all species: dense vegetation increases positions at risk**

Results

* bat presence < 10 s before or after vehicle pass

Results

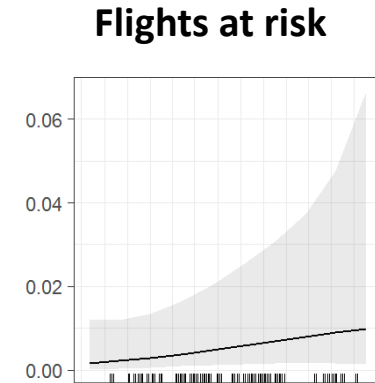

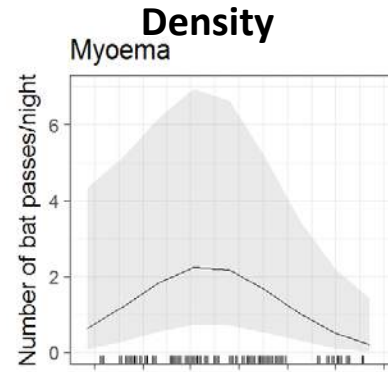

Results: effect of time of the year

Short-range echolocators (SRE)

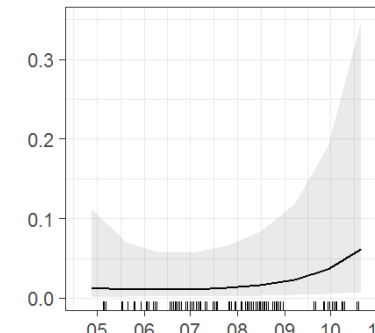

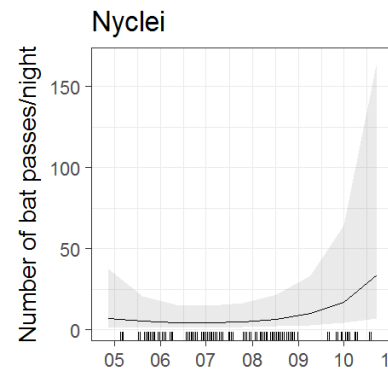

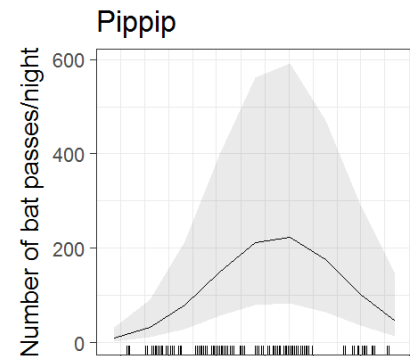

Mid-range echolocators (MRE)

Long-range echolocators (LRE)

Vehicle avoidance

Discussion

Recommendations to avoid road collisions

- **Bat density** ↘ with distance to tree foliage
 - **Site roads away from trees** 👍
 - Small trees = low primary productivity = low bat density ?
= low roost opportunities = low bat density ?

Distance to foliage = +2

Distance to foliage = - 3

Recommendations to avoid road collisions

- **Bat position at risk** ↗ when vegetation was dense
 - **Avoid dense vegetation** 👍
 - Tree rows = safer use of the “Edge effect”

Recommendations to reduce road collisions

- If roads sited in risky areas, test reduction measures, such as:
 - Vehicle speed reduction
 - (Cutting down trees to create a gap)

Thanks to my great supervisors:

Aurélie Coulon

Yves Bas

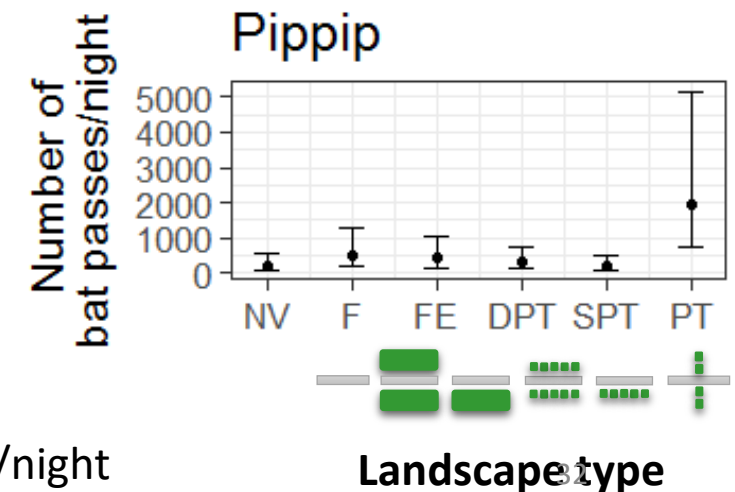

Many thanks to the people who helped me during fieldwork,
in particular Bruno Sanchez.

Merci!

Bat density

- Density = number of individuals / m²
- Our hypotheses:
 - Number of bat passes in a constant volume (i.e. microphone detection range) is proportional to density
 - Relation is not totally linear
 - But the majority of our sites did not have a very high activity

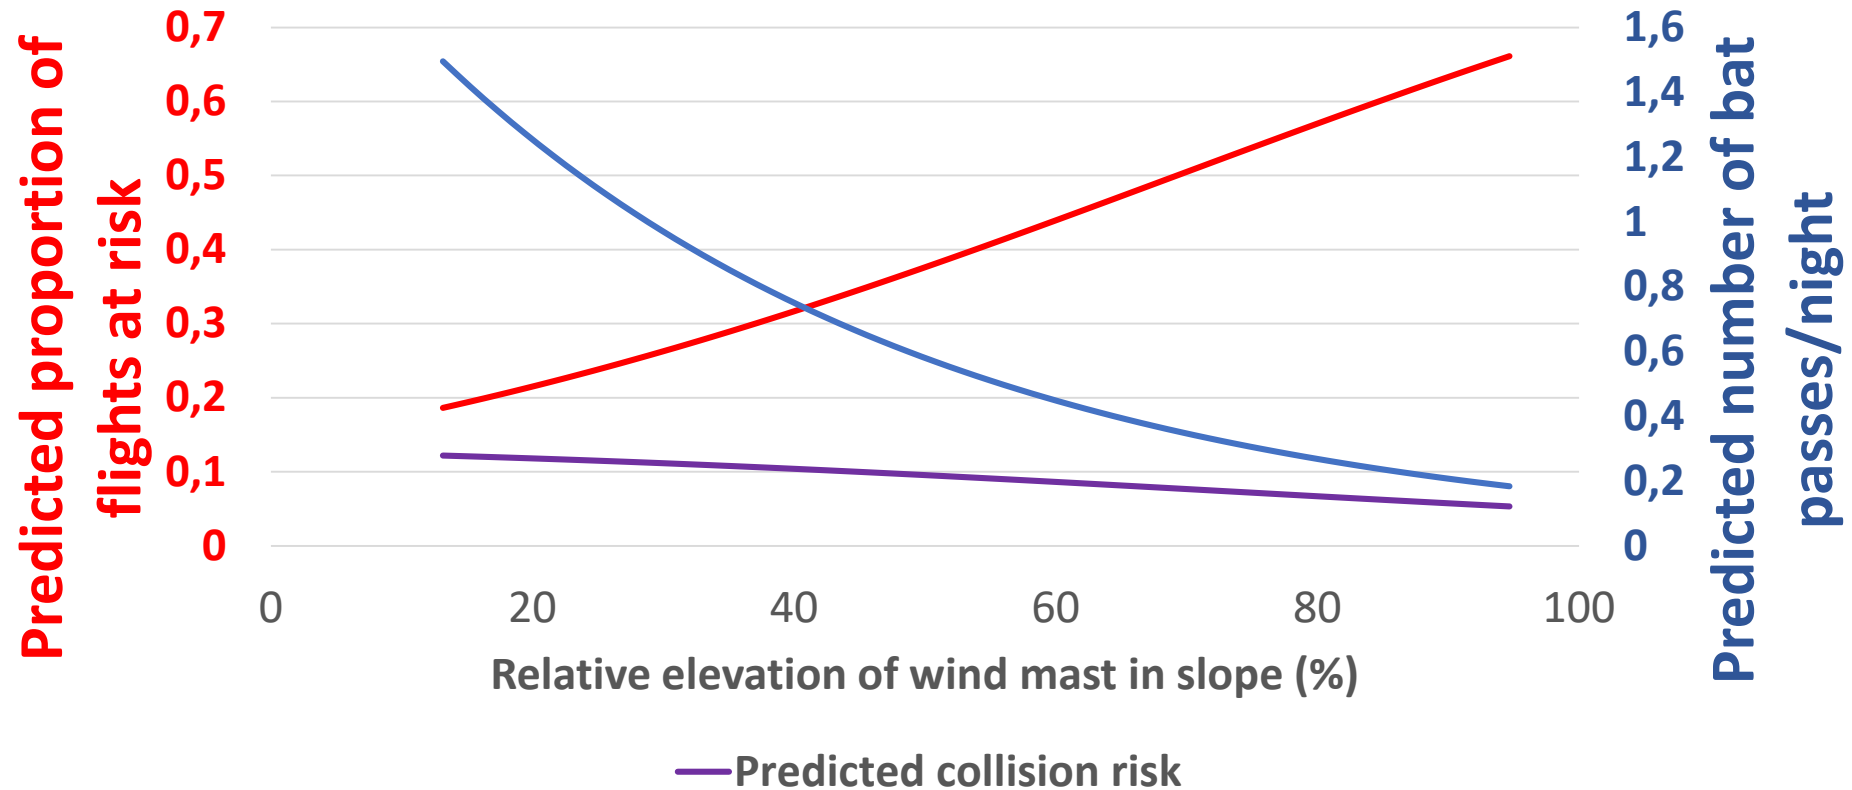

Conditional events of collisions

- Effect of the time of the year (*Nyctalus leisleri*)

Conditional events of collisions

- Effect of relative elevation of the wind mast (*Pipistrellus nathusii*)
